## APPS ON PHYSICS- Rutherford Scattering

**Reference: Simulation is available on Apps on Physics**

**Interface: Apps on physics >> Physics of atom >> Rutherford Scattering**

### Abstract:

Rutherford's scattering experiment explains the nuclear model of an atom. It shows that each atom has a nucleus where most of its mass is focused and electrons revolve around the nucleus in circular orbits.

The simulation is available on **Apps on physics >> Physics of atom >> Rutherford scattering** with the required parameters.

In the experimental configuration alpha particles are bombarded on thin gold foil and their scattering was influenced by electrostatic force. So the resulting hyperbolic (approximately) trajectories of particles led to conclude that atoms mostly have empty space with small, dense, positively charged nucleus at the centre.

### Keywords:

Rutherford scattering, gold foil, nucleus, electrostatic force, electrons.

**Aim of the Experiment:** To investigate the structure of the atom and provide evidence for the existence of nucleus.

### Introduction:

The atomic model has evolved over the time, starting from **Dalton's model** which proposed that atoms are indivisible, solid spheres. Then J.J. Thomson's **Plum pudding** model, where negative charges were spread out in a cloud of positive charge.

For the accurate and detailed analysis of atoms **Rutherford proposed** a new atomic model called Rutherford's **atomic model**, which is based on **Scattering of alpha particles** so this is also known as **Rutherford scattering**.

So In this experiment, we aim to verify the existence of a nucleus in every atom. Due to scattering of atoms deflection takes place. This deflection determines the trajectory and that will help to demonstrate the presence of a nucleus.

### Procedure:

1. Open **Apps on Physics**.
2. Tap on Rutherford scattering (for reference, see image-1).
3. On the right side, **Control** panel contains two buttons, **Clear trajectories** and **Start**.
4. Enter the atomic number (number of protons) for the scattering of alpha particles (for reference, see image-2).
5. As we vary the atomic number there will be change in the **Deflection angle**. We can also change velocity of alpha particle and impact parameter(distance between the scattering nucleus and the asymptotes of the hyperbola, (for reference see Image-3).
6. All results of the experiment are shown in the right side panel. (for reference, see image-4)
7. We can clear the trajectories or start the App using the buttons provided.(reference, see image-5)

**Calculations (reference table-2):**

- Projectile atomic number ( $Z_1$ ) = 2 (for alpha particle)
- Target atomic number ( $Z_2$ ) = 50 (for tin)
- Elementary charge ( $e$ ) =  $1.602 \times 10^{-19}$  C
- Vacuum permittivity ( $\epsilon_0$ ) =  $8.854 \times 10^{-12}$  F/m
- Impact parameter ( $b$ ) = 14.7 fm =  $1.47 \times 10^{-14}$  m
- Minimal distance ( $r_{\min}$ ) = 34.1 fm =  $3.41 \times 10^{-14}$  m
- Velocity of projectile ( $V$ ) = 30,000 km/s =  $3 \times 10^7$  m/s

**DEFLECTION ANGLE:**

$$\theta = 2 \cdot \arctan \left( \frac{Z_1 Z_2 e^2}{4\pi\epsilon_0 E} \cdot \frac{1}{b} \right)$$

**Energy Calculation in Joules**

$$E = \frac{Z_1 Z_2 e^2}{4\pi\epsilon_0 b r_{\min}}$$

$$E = \frac{(2)(50)(1.602 \times 10^{-19})^2}{4\pi(8.854 \times 10^{-12})(1.47 \times 10^{-14})(3.41 \times 10^{-14})}$$

$$E = 0.0455 \text{ J}$$

**CALCULATION FOR DEFLECTION ANGLE:**

$$\theta = 2 \cdot \arctan \left( \frac{Z_1 Z_2 e^2}{4\pi\epsilon_0 E} \cdot \frac{1}{b} \right)$$

Substituting the known values into this formula:

$$\theta = 2 \cdot \arctan \left( \frac{(2)(50)(1.602 \times 10^{-19})^2}{4\pi(8.854 \times 10^{-12})(0.0455)(1.47 \times 10^{-14})} \right)$$

$$\theta \approx 14.7^\circ$$

**Result:** Results are provided here by performing the experiment for different sets.

## Conclusion:

For the same atomic number as we increase the velocity keeping the impact parameter constant, both deflection angle and minimal distance decrease.

For the same atomic number as we increase the impact parameter keeping the velocity constant, the deflection angle decreases and minimal distance increases.

1. **Atomic Number (Z):** When the atomic number increases, the deflection angle increases. A higher atomic number results in a stronger Coulomb force, causing larger deflection of the projectile.
2. **Velocity (v):** As the velocity of the projectile increases, the deflection angle decreases. Faster particles interact less strongly with the nucleus, leading to smaller deflection angles.
3. **Impact Parameter (b):** Increasing the impact parameter leads to a smaller deflection angle. A larger impact parameter means the projectile does not come as close to the nucleus, resulting in a weaker interaction and smaller deflection.

### Changing Impact Parameter (keeping velocity constant):

**Deflection Angle:** As the impact parameter increases, the deflection angle decreases. A larger impact parameter means the particle passes farther from the nucleus, resulting in a smaller angle of deflection.

**Minimal Distance:** The minimal distance increases with the impact parameter. A larger impact parameter means the particle will not approach the nucleus as closely.

### Changing Velocity (keeping impact parameter constant):

**Deflection Angle:** As velocity increases, the deflection angle decreases.

A faster moving particle has more kinetic energy and is less affected by the Coulomb force, leading to a smaller deflection.

**Minimal Distance:** The minimal distance decreases with increased velocity.

A faster moving particle can approach the nucleus more closely before being deflected.

The Rutherford scattering experiment confirms the existence of a small, dense, positively charged nucleus at the centre of the atom. The results validate Rutherford's model by showing that alpha particle deflections are due to the Coulomb force between the nucleus of gold foil and other metals with alpha particles, proving that most of the atom's mass and charge are concentrated in its core.

## Image 1: Rutherford Scattering Practical Demonstration

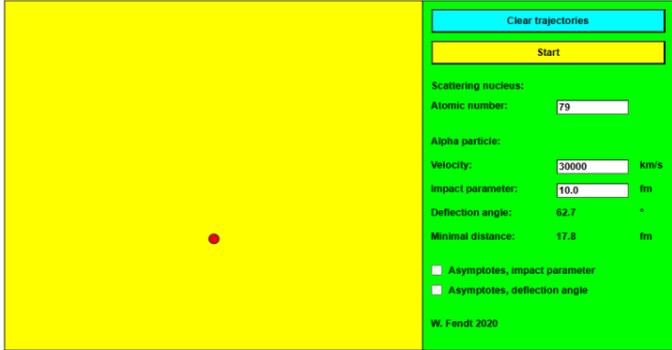

**Rutherford Scattering**

The New Zealand-born physicist Ernest Rutherford carried out a famous experiment on the structure of the atom in 1911. He bombarded a thin gold foil with alpha rays (helium-4 nuclei of high velocity, as they occur in many radioactive materials) and analysed the distribution of the **deflection angles** (scattering angles). This angle describes the changed motion direction of an alpha particle passing an atomic nucleus of the foil.

This app simulates the motion of an alpha particle under the influence of the repulsive electrostatic force (Coulomb force) exerted by a single atomic nucleus of the gold foil. The trajectory of the particle is (approximately) a hyperbola, with the target nucleus as one of the focal points of this hyperbola.

The control panel on the right side has two buttons, one to clear the particle trajectories, and one to "start" the motion of a single alpha particle. For the scattering nucleus, the atomic number (number of protons) can be entered. For the alpha particle, you can vary the velocity and the **impact parameter** (distance between the scattering nucleus and the asymptotes of the hyperbola). Inputs outside the permitted range are automatically changed. Below the input fields, you can read the values of the deflection angle and the minimal distance. The femtometer unit (fm) is used for this purpose:  $1 \text{ fm} = 10^{-15} \text{ m}$ . Two option fields are used to specify whether asymptotes, impact parameter, and deflection angle should be displayed apart from the particles and orbits involved.

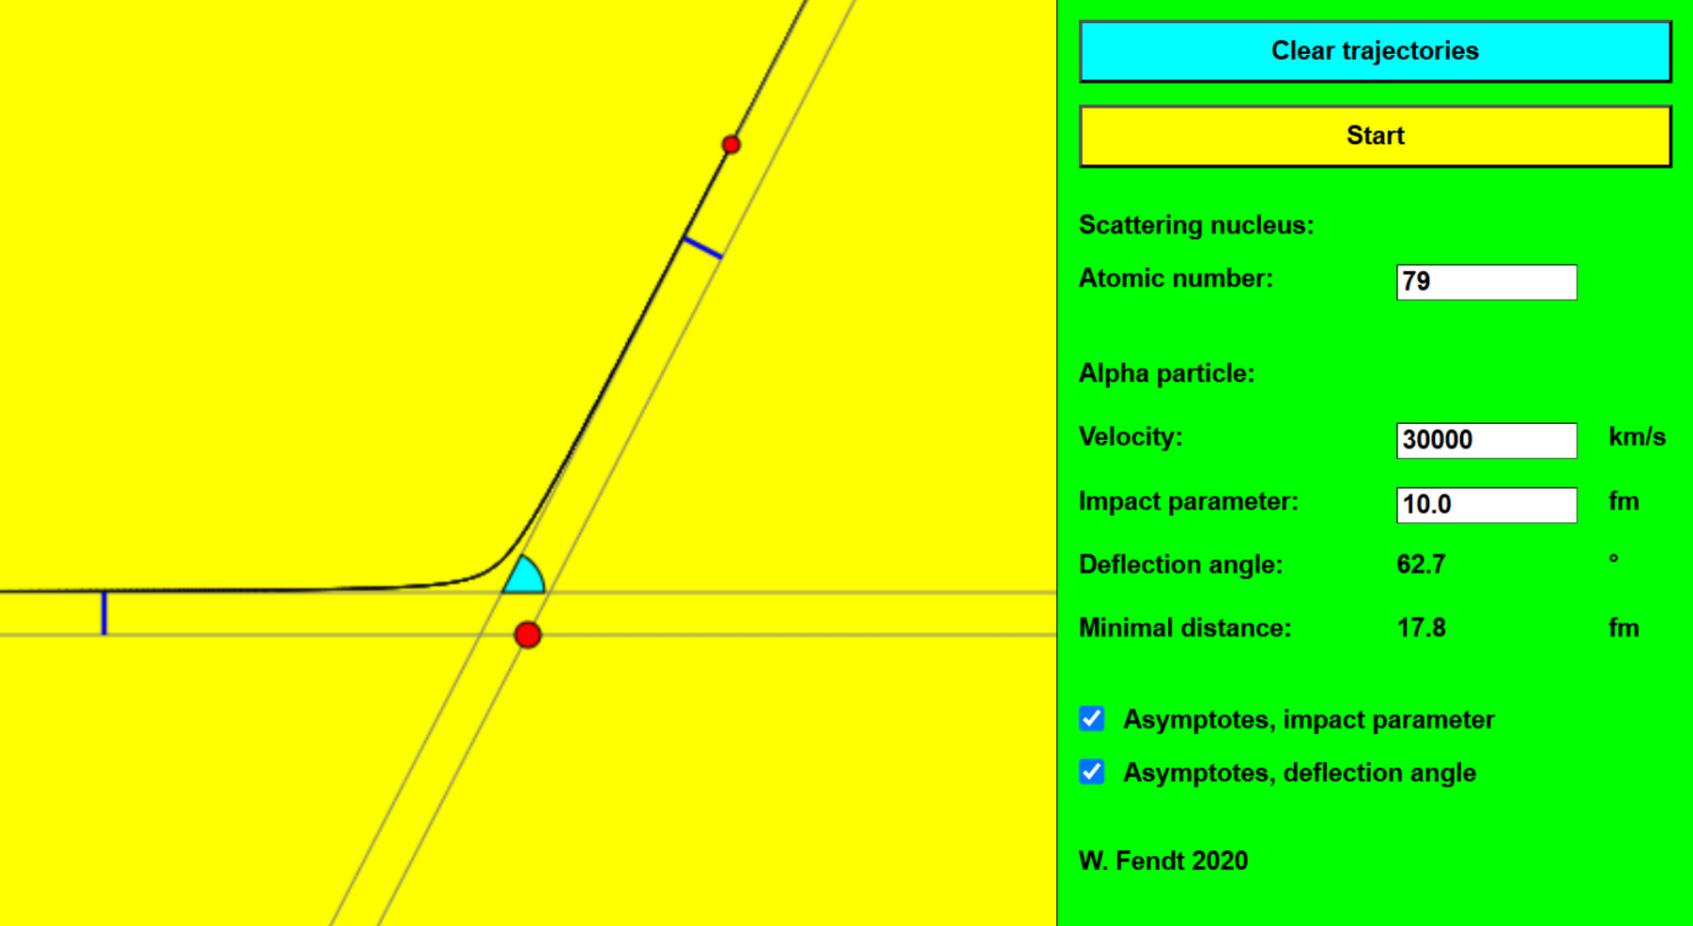

W. Fendt 2020

During the evaluation of the experiment, the measured distribution differed significantly from the calculated distribution for small deflection angles (i.e. large values of the impact parameter), as expected. These deviations can be explained by the influence of the electrons.

For large deflection angles (small impact parameters), the measured distribution matched the precalculated distribution very well. This fact proves that the positive charge inside the atom (i.e. the atomic nucleus) has a very small extension. In other words: Atoms are mostly "empty".

## Image 2: simulation is performed for "Z=79".

**Clear trajectories**

**Start**

**Scattering nucleus:**

**Atomic number:** 79

**Alpha particle:**

**Velocity:** 30000 km/s

**Impact parameter:** 10.0 fm

**Deflection angle:** 62.7 °

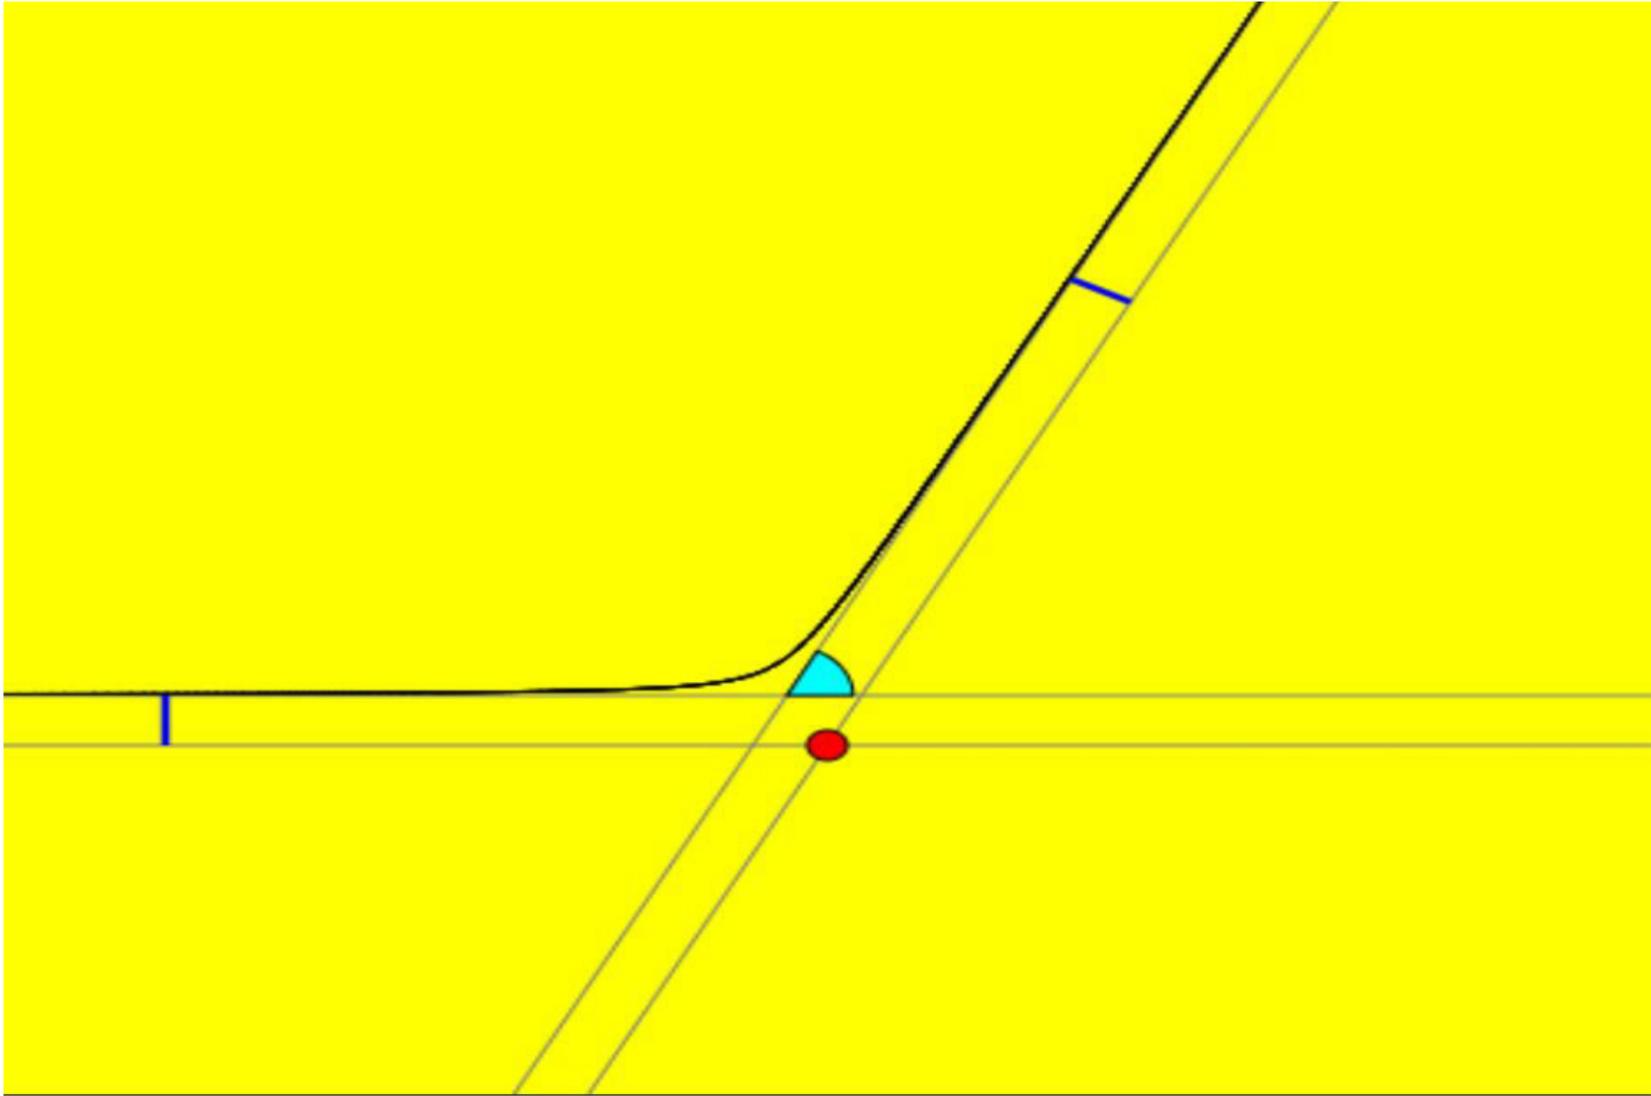

**Minimal distance:** 17.8 fm
